TITLE : STATOR FOR RELUCTANCE MOTOR
 AND DEVICE FOR FORMING THE
 SAME

ABSTRACT : PROBLEM TO BE SOLVED: To provide a cylindrical stator for reluctance motor in which no deviation occur among electric poles, when the stator is formed by coupling a plurality of electric pole members with each other and which can be rotated smoothly in such a state that the stator hardly vibrates.

SOLUTION: A stator for reluctance motor is formed by coupling a plurality of electric pole members 2 each having a yoke section 2b and a projecting section 2a which is protruded inward in the radial direction from the yoke section 2b for forming a salient pole into cylindrical shape with each other. When each electric pole member 2 is formed from a base material 4 for stator formed integrally into a cylindrical shape, the base material 4 is fractured in to axial direction so that the parted surfaces 5 formed by the fracture become surfaces having notches of fine recesses and projections.
